

## **Guanidine compounds and their use as binding partners for 5-HT5 receptors**

### **Field of the invention**

The present invention relates to guanidine compounds and the use of guanidine compounds as binding partners for 5-HT5 receptors for the treatment of diseases that are modulated by a 5-HT5 receptor activity, in particular for the treatment of neurodegenerative and neuropsychiatric disorders as well as the signs, symptoms and dysfunctions associated therewith.

### **Background of the invention**

At least seven different receptor classes mediate the physiological activities which are attributed to an involvement of the neurotransmitter serotonin (5-hydroxytryptamine, or 5-HT for short). They are designated according to an internationally recognized classification as 5-HT1, 5-HT2, 5-HT3, 5-HT4, 5-HT5, 5-HT6 and 5-HT7. The majority of these classes additionally include further distinguishable receptor sub-types. For example, receptors belonging to the 5-HT1 class can be further subdivided in at least five sub-classes and are termed 5-HT1A, 5-HT1B, 5-HT1C, 5-HT1D and 5-HT1E (Boess, Martin; *Neuropharmacology* 33:275-317 (1994)).

The 5-HT5-class was first described by Plassat et al., *The EMBO Journal* Bd. 11 Nr. 13, S. 4779-4786 (1992). One distinguishes between 5-HT5A and 5-HT5B receptors (Erlander et al., *Proc. Natl. Acad. Sci. USA* 90:3452-3456 (1993)). There exists only minimal sequence homology between 5-HT5 and other 5-HT receptors, and the pharmacological profile of these receptors is markedly different. 5-HT5 receptors can be localized with the help of molecular biological techniques in the olfactory bulb, in the hippocampus, in the cortex, in the cerebral ventricles, in the corpus callosum and in the cerebellum. It was shown by immunohistochemical methods that 5-HT5 receptors are expressed in different regions of the brain (Oliver et al. *Brain Res* 2000, 867, 131-142 ; Pasqualetti et al. *Mol Brain Res* 1998, 56, 1-8)). These 5-HT5 receptors can on the one hand modulate functions of the brain directly or indirectly, but on the other hand they may also participate in mechanisms involved in neuropathological, neurodegenerative and neuropsychiatric diseases. 5-HT5 receptors were also localized in astrocytes (Carson et al., *GLIA* 17:317-326 (1996)). Astrocytes lie directly on the basal membrane of

brain capillaries of the blood brain barrier and an abnormal astrocyte-endothelium-structure is associated with a loss of the blood brain barrier. The exact significance of astrocytes is unclear, but they seem to assume transport roles and connective functions. Reactive astrocytes were observed in connection with reactive gliosis in a series of pathological brain changes and neuropsychiatric diseases. These astrocytes modify their morphology as a result of brain injuries. The protein expression pattern changes and growth factors are produced. *In-vitro* studies on cultivated astrocytes showed 5-HT<sub>5</sub> receptor mediated responses. For this reason, it is on the one hand assumed that the 5-HT<sub>5</sub> receptor plays a role in recovery processes of the brain after disorders; on the other hand, it cannot be excluded that they contribute to the development of damage or even to an augmentation of damage.

Diseases of the CNS currently affect large sections of the population. The numbers of patients are continually rising, especially due to the increase of older people. Neuropathological conditions such as cerebral ischemia, stroke, epilepsy and seizures in general, chronic schizophrenia, other psychotic diseases, depression, states of anxiety, bipolar disorders, dementia, in particular Alzheimer dementia, demyelinating diseases, in particular multiple sclerosis, and brain tumors, lead to damage of the brain and to the neuronal deficits associated therewith. Up to now, therapeutic treatments of the neurodegenerative and neuropsychiatric disorders described have been directed to different membrane receptors with the goal of compensating deficits in neurotransmission processes. Neuroprotective effects with different serotonergic compounds have been achieved in animal models for neuropathological conditions such as ischemia, stroke and excitotoxicity; in some cases beneficial effects on mood disorders, such as depression or states of anxiety, could be observed. For example 5-HT<sub>1A</sub> agonists such as buspiron, or the compound 8-hydroxy-2-(di-n-propylamino)tetraline (8-OH-DPAT), characterized as a selective 5-HT<sub>1A</sub> receptor-ligand, are noteworthy in this regard. However, these agents alleviate the neurological deficits described only under certain conditions; an effective therapy for these diseases does not yet exist at the present time

A further neuropathological disease affecting large segments of the population, is migraine. In most cases, migraine manifests itself in recurring headaches, affecting an estimated 8 million people, i.e. 3-5 % of all children, 7% of all men and 14% of all women. Although a genetic predisposition is propagated, the causes seem to be

complex. (Diener H.C. et al., *Arzneimitteltherapie* 15:387-394 (1997)). Two hypotheses dominate. The vessel theory, known for a long time, suggests a dilation process of the inner and outer cerebral vessel system as a cause. The neurogenic theory is based on a release of vasoactive neurotransmitters, primarily neuropeptides, such as substance P and neurokinin from axons of the vasculature, as a result of a stimulation of certain ganglia which innervate brain tissue, which supposedly leads to inflammatory reactions and thus to pain.

A causal therapy for the treatment of migraines does not yet exist at the present time. Two different treatment methods are currently employed: a first, prophylactic therapy for the prevention of recurring migraine attacks and a second, symptomatic therapy for suppressing acute symptoms during attacks. Migraine-specific agents such as Sanmigran<sup>R</sup>, Nocerton<sup>R</sup>, Desernil<sup>R</sup> and Vidora<sup>R</sup>, as well as other agents typically used for other indications, such as beta-blockers, anti-emetic agents such as Sibelium<sup>R</sup>, anti-depressives such as Laroxyl<sup>R</sup>, or anti-epileptic agents such as Depakin<sup>R</sup>, are prophylactically administered. In the context of acute therapy, one gives analgesics, such as Aspirin<sup>R</sup>, Paracetamol<sup>R</sup> or Optalidon<sup>R</sup>, non-steroidal anti-inflammatory agents, such as Cebutid<sup>R</sup>, Voltaren<sup>R</sup>, Brufen<sup>R</sup>, Ponstyl<sup>R</sup>, Profenid<sup>R</sup>, Apranx<sup>R</sup> and Naprosin<sup>R</sup> against the pain and inflammation, ergotalkaloids, such as ergotamine, dihydroergotamine, which can trigger a vasoconstriction, or substances of the triptan-family, such as sumatriptan, Naramig<sup>R</sup>, and AscoTop<sup>R</sup> with high affinity for 5-HT<sub>1D</sub> receptors. The latter substances function as agonists and block vasodilation.

The agents described are however not optimally suited for the treatment of migraines. Non-opioid analgesics often have side effects. The complex mode of action of ergotalkaloids leads to side effects such as hypertonia and gangrene due to the strong peripheral vasoconstriction. Compounds belonging to the triptan-family also are not completely satisfactory in their function. (Pfaffenrath V. *Münch. Med. Wschr.* 625-626 (1998)).

The use of 5-HT<sub>5</sub> receptor ligands in general for the treatment of migraines and other cerebralvascular diseases, is described in WO 00/041472, and in WO 00/041696 for the treatment of neurodegenerative and neuropsychiatric diseases.

Guanidine compounds have not been used as 5-HT<sub>5</sub> ligands up to now.

Substituted guanidines are generally known as H<sub>2</sub>-antagonists, as inhibitors of the H<sup>+</sup>K<sup>+</sup>-ATPase, inhibitors of the secretion of stomach acid, and in these capacities as a means for treating PUD-syndrome (Peptic Ulcer Disease). The most diversely substituted thiazole-guanidines are generally described in the literature as compounds with anti-viral, bactericidal, anti-microbial and/or anti-inflammatory affect, as protease-inhibitors or vitronectin-antagonists.

WO-9850373 describes *N*-substituted *N*-[4-(phenoxyphenyl)-1,3-thiazole-2-yl]guanidine and their use as bactericides. In WO-9605187 and EP-545376 the preparation of substituted 4-(3-aminomethylphenyl)-2-thiazolylguanidines and their use as H<sub>2</sub> receptor antagonists is described. JP-59225172 generally describes *N*-alkyl-substituted 4-phenylthiazolguanidines as H<sub>1</sub> and H<sub>2</sub> receptor antagonists and their use as inhibitors of stomach acid secretion. EP-259085 also describes the preparation of 4-hetaryl-substituted thiazolguanidines, especially corresponding pyrrolyl- and indolyl-derivatives for the treatment of PUD syndrome. JP-59225186 and JP-59036674 describe 4-hetaryl-substituted thiazolguanidines, especially 2-furyl- and 2-pyridyl-derivatives, and their anti-secretory properties.

In the Journal of Chemical and Engineering Data 1978, 23 (2), 177-8, N-aryl-N'-2-(thiazolyl-, naphthothiazolyl-, benzothiazolyl)guanidines are described as substances with anti-malaria-effect and/or analgesic properties. In Bioorg.Med.Chem.Lett. 2000 (10), 265-268, N-[2-(2-methoxyphenyl)ethyl]-N'-1,3-thiazole-2-ylguanidine is described in the context of bioisosteric modifications of PTT-HIV-1 RT-inhibitors, but the compound did not show any demonstrable biological activity. Differently substituted thiazolguanidines are described in the following literature citations as anti-microbial substances with activity against *heliobacter pylori*: 2-(substituted guanidino)-4-arylthiazole and Aryloxazole in J. #### **Optical isomers – Diastereomers – Geometric isomers - Tautomers**

The guanidine compounds of the formula I or IA or their salts, can have at least one asymmetric centre and can exist as racemates and racemic mixtures, single enantiomers, diastereomeric mixtures and single diastereomers. The present invention includes all of these stereoisomeric forms of the guanidine compounds of formula I or IA.

The guanidine compounds of formula I or IA can be separated into their single stereoisomers by conventional methods, e.g. by fractional crystallization from a suitable solvent, e.g. methanol or ethyl acetate or from a mixture thereof or by chiral chromatography using an optically active stationary phase. The absolute stereochemistry can be determined by x-ray crystallography of the crystalline products or crystalline intermediates which, if necessary, can be derivatized with a reaction component which contains an asymmetric center of a known absolute configuration.

Alternatively, any stereoisomer of a guanidine of the formula I or IA can be obtained by stereospecific synthesis using optically pure starting materials or reaction components with known absolute configuration or by asymmetric synthesis methods.

The use of an enantiomerically- or diastereomerically pure compound is preferred.

Particularly the guanidine compounds of the formula I or IA described here can also exist as different tautomers of the guanidine group wherein, as is clear to a person of ordinary skill in the art, the kind of tautomerism depends on the nature of the moieties R1, R2 and R3. Other tautomers, such as keto-enol tautomers, can also exist. All single possible tautomers, as well as mixtures thereof, are included in the guanidine compounds of formula I or IA.

The term "disorder" in the sense according to the invention, refers to anomalies that are generally seen as disease states and which manifest themselves in the form of certain

signs, symptoms and/or dysfunctions. The treatment can be directed to single disorders, in other words, anomalies or disease states, but multiple anomalies, which can possibly be causally connected to one another, can also occur together as patterns, in other words, syndromes, which can be treated according to the invention. This state can be temporary, progressive or permanent.

Compounds of the present invention can be used for the treatment or prevention of different diseases, in which 5-HT<sub>5</sub> receptors participate in the emergence and/or progression, i.e. diseases that are modulated by a 5-HT<sub>5</sub> receptor activity, such as mental disorders. According to the „American Psychiatric Association DSM-IV, Diagnostic and Statistical Manual of Mental Disorders, 4th ed., 1994“, examples of such mental disorders are: attention disorders and socially disturbing behavior, learning disorders, delirium, dementia and amnesia and other cognitive disorders; disorders in connection with different substances, such as, for example, disorders in connection with alcohol consumption and alcohol induced disorders, withdrawal symptoms; schizophrenia and other psychotic disorders such as, for example schizophreniform disorder, schizoaffective disorder and delusional disorder; substance-induced psychoses; paranoid disorders, disorders induced by neuroleptics; affective disorders such as, for example, depressive disorders (major depression, dysthymic disorder, seasonal-related disorder, unspecified depressive disorder), bipolar disorders (bipolar I disorder, bipolar II disorder, cyclothymic disorder, unspecified bipolar disorder, affective disorder induced by substances (amphetamine or amphetamine-like substances), unspecified affective disorder); disorders in connection with stress, such as, for example, acute stress disorder; anxiety disorders, such as, for example, panic disorders without agoraphobia, panic disorder with agoraphobia, agoraphobia without panic disorder in the pre-history, specific phobia, social phobia, compulsive disorder, post-traumatic stress disorder, acute stress disorder, generalized anxiety disorder, substance-induced anxiety disorder; somatoform disorders such as, for example, somatization disorder, unspecified somatoform disorder, conversion disorder, pain disorder, eating disorders, sleeping disorders such as, for example, primary sleeping disorders (dyssomnia, parasomnia), sleeping disorders in connection with another mental disorder.

The subject matter of the invention is also, in particular, the use of guanidine compounds I and IA for the treatment of neuropathological, neuropsychiatric and neurodegenerative disorders.

By neuropathological disorders are, are understood disorders which are accompanied by neurological deficits, i.e. a condition characterized by symptoms of neurological loss.

According to the invention, the treatment of neurodegenerative and/or neuropsychiatric disorders is preferred. These disorders occur particularly in neuropathological disease patterns, which normally cause brain damage, for example, cerebral ischemia, stroke, epilepsy and seizures in general, chronic schizophrenia, other psychotic diseases, depression, states of anxiety, bipolar disorders, dementia, in particular Alzheimer dementia, demyelinating diseases, in particular multiple sclerosis, brain tumours and general inflammatory processes. A further neuropathological disorder is migraine as well as the signs, symptoms and dysfunctions associated therewith.

According to a further aspect of the present invention, neuropathological disorders are treated which are attended by a glial reaction. The use, according to the invention, relates in particular to the modulation of a glial reaction. An advantageous effect of the binding partners is apparent in the preventative or acute treatment of neurological deficits observed in patients suffering from psychiatric diseases, such as epilepsy, psychosis, e.g. psychoses of the acute exogenous reaction type or accompanying psychoses, e.g. psychoses of organic or exogenous cause, e.g. following trauma, primarily brain lesions and diffuse brain damage, by metabolic disorders, infections and endocrinopathies; endogenous psychoses, such as schizophrenia, as well as schizo-like and delusional disorders; affective disorders, such as depression, mania or manic depressive states; as well as hybrid forms of the psychoses set out above; senile dementia and senile dementia of the Alzheimer type, as well as in the treatment or prevention of demyelination processes.

The guanidine compounds according to the invention are especially effective in the treatment of ischemic damage, e.g. due to brain and spinal cord trauma, as well as vessel occlusion or heart failure. Noteworthy here is primarily apoplexia (synonym: apoplexia cerebri, cerebral or apoplectic insult, stroke). According to the invention, the following are treatable: transitory-ischemic attacks, reversible ischemic neurological deficits, prolonged reversible ischemic neurological deficits, partial reversible ischemic neurological symptoms and signs and also persistent complete brain infarcts. According to the invention, the treatment of acute forms is especially advantageous.

The forms of neuropathological disorders preferentially treated according to the invention, are due to one or more of the following listed changes in nerve tissue: degeneration or death of neurons, in particular of the ganglia cells, e.g. tigrolysis, blurring of the nuclear membrane, cell shrinking, cytoplasm vacuolisation and incrustation, parenchyma necrosis of the brain, edema of the brain, changes of neurons due to lack of oxygen, atrophy, morphological changes such as demyelination, in particular myelinic degeneration, perivascular infiltrates, gliotic (German: "gliöse") proliferation and/or glia scars; degeneration of the substantia nigra.

The indication to be treated according to the invention is often characterized by a . progressive development, i.e. the conditions described above change over the course of time, the severity normally increases and, possibly, conditions can merge into one another or further conditions can join existing conditions. By the treatment according to the invention of neuropathological, neuropsychiatric or neurodegenerative disorders or the conditions causing these, it is possible to treat a series of further signs, symptoms, and/or dysfunctions which are connected with these disorders, i.e. especially which accompany the disease states described above. These include, e.g., shock lung, brain nerve loss, e.g., retrobulbar neuritis, eye muscle paralysis, scanning speech, spastic paralyzes, symptoms of the cerebellum, disorders of sensibility, bladder and rectum, euphoria, dementia, hypokinesia and akinesia, poverty of movement, shuffling gait, bent posture of rump and limbs, pro-, retro- and lateropulsion, tremor, lacking mimic, monotone speech, depressions, apathy, labile or rigid affectivity, impeded spontaneity and decisiveness, slowed thinking, reduced associative ability; muscle atrophy.

A treatment in the sense according to the invention includes not only the treatment of acute or chronic signs, symptoms and/or dysfunctions, but also a preventative treatment (prophylaxis), in particular as a relapse or phase prophylaxis. The treatment can be symptomatically oriented, for example as a suppression of symptoms. It can take place for a short time, be intermediately oriented, or can also be a long-term treatment, for example within the context of a maintenance therapy.

The term "binding partner for 5-HT<sub>5</sub> receptors" describes substances which bind to 5-HT<sub>5</sub> receptors and therefore may also be termed 5-HT<sub>5</sub> receptor ligands.

By binding, is understood every molecular interaction between the binding partner and the receptor, in particular under physiological conditions. These are normally classical

interactions, to which electrostatic attraction, hydrogen-bonding, hydrophobic bonds, van-der-Waals forces or coordinative bindings of the sort seen with metal complexes belong. In addition to the reversible molecular interactions named above, irreversible interactions between binding partner and receptor such as e.g. covalent bindings, may also be considered.

Guanidine compounds according to the invention can competitively inhibit the binding of comparative binding partners, such as 5-HT (5-hydroxytryptamine) or 5-CT (5-carboxamidotryptamine), to 5-HT<sub>5</sub> receptors. The term competitive inhibition is understood such that the guanidine compounds according to the invention, compete with a comparative binding partner, in the present case e.g. 5-HT or 5-CT, for binding to the receptor.

According to a further embodiment, guanidine compounds according to the invention non-competitively inhibit the binding of comparative binding partners such as 5-HT (5-hydroxytryptamine) or 5-CT (5-carboxamidotryptamine), to 5-HT<sub>5</sub> receptors. Non-competitive inhibition is understood such that guanidine compounds according to the invention modulate, in particular reduce the binding affinity of the binding of a comparative binding partner, in the present case e.g. 5-HT or 5-CT, to the receptor.

At least for the case of competitive inhibition, in other words in the case of reversible binding, the principle applies that the displacement of one binding partner by another increases with decreasing binding affinity of the one or increasing binding affinity of the other, with regard to the receptor. Guanidine compounds, according to the invention therefore expeditiously have a high binding affinity for 5-HT<sub>5</sub> receptors. Such a binding affinity allows, on the one hand, an effective displacement of naturally occurring binding partners for 5-HT<sub>5</sub> receptors, such as, for example, serotonin (5-hydroxytryptamine, 5-HT) itself, wherein the required concentration of guanidine compound according to the invention for a certain amount of this binding partner to bind to 5-HT<sub>5</sub> receptors decreases with increasing binding affinity. With regard to the medical application, those guanidine compounds are therefore preferred whose binding affinity is so large that these compounds can be administered in justifiable amounts within the framework of an effective medical treatment.

One possibility to express the binding affinity is offered by the competition experiments mentioned above, with which one determines *in-vitro* the concentration of guanidine

compound according to the invention which displaces another comparative binding partner from the receptor binding site by 50% (IC<sub>50</sub>-values). In this way one can also evaluate the competitive inhibition of the binding of 5-HT to 5-HT<sub>5</sub> receptors, such that preferred guanidine compounds according to the invention have half-maximal inhibition constants IC<sub>50</sub> of less than 10<sup>-5</sup> M, preferably less than 10<sup>-6</sup> M and in particular, less than 10<sup>-7</sup> M. The binding affinity of guanidine compounds according to the invention can also be expressed via the inhibition constant K<sub>i</sub>, which is generally also determined with *in-vitro* competition experiments. For the binding to 5-HT<sub>5</sub> receptors guanidine compounds according to the invention preferably exhibit K<sub>i</sub>-values of less than 10<sup>-6</sup> M, preferably less than 10<sup>-7</sup> M and particularly preferred less than 10<sup>-8</sup> M.

Useful binding partners can bind to 5-HT<sub>5</sub> with a lower, a substantially identical, or a higher affinity than to a certain receptor different from 5-HT<sub>5</sub>. As such, binding partners for 5-HT<sub>5</sub> receptors in the context of the use according to the invention include in particular those whose binding affinity to 5-HT<sub>5</sub> receptors is so high as compared to the affinity for 5-HT-receptors, that they are suitable in an advantageous manner for the use according to the invention. This does not necessarily require a comparatively more selective binding to 5-HT<sub>5</sub> receptors, although selective binding partners for the 5-HT<sub>5</sub> receptors are a special embodiment of the present invention.

For example, one can use binding partners of high affinity not only to 5-HT<sub>5</sub>, but also to other 5-HT receptors. In this context, high affinity means K<sub>i</sub>-values normally in the range of 10<sup>-10</sup> M to 10<sup>-6</sup> M. According to a special embodiment, guanidine compounds in the high affinity range for 5-HT receptors have a binding profile which is characterized by a binding affinity to 5-HT<sub>5</sub> which, in comparison to other binding affinities of this range, is substantially identical or only slightly less. Factors of 10 or less can be advantageous.

Guanidine compounds according to the invention have binding affinities for 5-HT<sub>5</sub> receptors which are larger than for one or more 5-HT receptors different than 5-HT<sub>5</sub>, thus, in particular, the receptors classified in the 5-HT receptor classes 5-HT<sub>1</sub>, 5-HT<sub>2</sub>, 5-HT<sub>3</sub>, 5-HT<sub>4</sub>, 5-HT<sub>6</sub> and 5-HT<sub>7</sub> given above. If the binding affinity of a binding partner for 5-HT<sub>5</sub> receptors is larger than that for a 5-HT receptor different than 5-HT<sub>5</sub>, one speaks of a selective binding of these binding partners to 5-HT<sub>5</sub> receptors, relative to the 5-HT receptor different from 5-HT<sub>5</sub>. Special binding partners are those whose binding affinity for 5-HT<sub>5</sub> receptors is larger than for at least one 5-HT receptor. Guanidine compounds whose binding affinity for 5-HT<sub>5</sub> receptors is larger than for all of the 5-HT receptors

different from 5-HT<sub>5</sub>, represent a further special class of guanidine compounds according to the invention.

The term „selectivity“ is understood as the characteristic of a binding partner to preferably bind to 5-HT<sub>5</sub> receptors. It is decisive for the selectivity described above that the binding affinities for, on the one hand, 5-HT<sub>5</sub> receptors and, on the other hand, for one or more 5-HT receptors different from 5-HT<sub>5</sub>, are sufficiently different. Preferable are differences in affinity according to which binding affinity proportions of at least 2, more preferred of at least 5, especially preferred of at least 10, preferably of at least 20, especially preferred of at least 50 and in particular of at least 100 exist.

According to a further embodiment, guanidine compounds according to the invention bind, with reference to one or more 5-HT receptors different from 5-HT<sub>5</sub>, selectively to 5-HT<sub>5</sub> receptors with the advantageous binding affinities described above.

According to a further embodiment, guanidine compounds according to the invention bind, with reference to all 5-HT receptors different from 5-HT<sub>5</sub>, selectively to 5-HT<sub>5</sub> receptors with the advantageous binding affinities described above.

Guanidine compounds which bind to 5-HT<sub>5</sub> receptors with the affinities and selectivities described above, and which are expressed in glia cells and in particular by astrocytes are especially preferred. According to the invention, the human receptor variant is a preferred target for guanidine compounds according to the invention.

The binding of guanidine compounds according to the invention to 5-HT<sub>5</sub> receptors is coupled to an effector function. Binding partners can be agonistic or antagonistic as well as partially agonistic and/or partially antagonistic in function. According to the invention, compounds which completely or partially imitate the activity of 5-HT to 5-HT<sub>5</sub> receptors, are termed agonists. According to the invention, guanidine compounds which can block the agonistic activity of 5-HT to 5-HT<sub>5</sub> receptors are termed antagonists.

According to a special embodiment of the present invention, guanidine compounds are employed whose binding, at least to 5-HT<sub>5</sub> receptors of h5-HT<sub>5</sub>-transfected CHO or HEK 293 or SHSY-5Y cells effects a change of the agonist-induced stimulation of the binding of GTP to membrane-bound G-proteins, a change in intracellular calcium levels,

a change in the agonist-induced induction of phospholipase C activity and/or a change in the cAMP-production. Concerning the change in intracellular calcium levels, the use of guanidine compounds which effect an increase in intracellular calcium levels represents a special embodiment of the invention. This embodiment also includes guanidine compounds which are efficacious in known animal models for neurodegenerative and neuropsychiatric processes.

Preferred are guanidine compounds which, with reference to their effector function in the sense described above, are selective for 5-HT<sub>5</sub> receptors.

#### **Forms of administration and formulation**

Carriers or adjuvants which are pharmaceutically acceptable are those which are known for use as such in the field of pharmacy and neighboring fields, in particular, those listed in relevant medicine books (for example, DAB (Deutsches Arzneimittelbuch), Ph. Eur. (Pharmacopoeia Europaea), BP (Baccalaureus Pharmaciae), NF (National Formulary), USP (United States Pharmacopoeia), as well as other carriers whose properties do not rule out a physiological application.

Excipients can be solid, semisolid or liquid materials, which serve as the vehicle, carrier or medium for the active agent. The admixing of further adjuvants normally occurs in a common manner. Steps to confer a shape, optionally in connection with mixing processes, can be performed, for example, granulation, compression and the like.

The use according to the invention of the active agents according to the invention includes in the context of the treatment a method. In this regard, an efficacious amount of at least one guanidine compound of the Formula I or IA is administered to the individual to be treated, preferably a mammal, in particular a human and also livestock or a pet, normally formulated corresponding to pharmaceutical practice.

The invention also relates to the preparation of agents for the treatment of an individual, preferably a mammal, in particular a human, livestock or a pet.

The guanidine compound of Formula I or IA or a corresponding pharmaceutical composition can be administered orally, rectally, topically, parenterally, including subcutaneously, intravenously, and intramuscularly, ocularly, pulmonarily, or nasally. An oral administration is preferred.

Effective dosing of the active agent may depend on the type of guanidine compound, the type of administration, the sickness to be treated and the severity of the sickness to be treated. Such an effective dosing of the active agent can be determined by one of ordinary skill in the art in the field.

The dosing depends on the age, condition and weight of the patient as well as the type of application. Normally the daily dose of active agent will be between about 0.5 and 100 mg/kg body weight for oral administration and between about 0.1 and 10 mg/kg body weight for parenteral administration.

### **Preparation of the Guanidine Compounds**

The guanidine compounds according to the invention can be prepared analogously to methods known in the literature, which are known to one of ordinary skill in the art. The synthesis of guanidine is generally described in J. Org. Chem. 1997, 9, 1053; Tetrahedron 1999, 55 (10), 713; Tetrahedron Letters 1999, 40, 53; J. Org. Chem. 2000, 65, 8080 and the literature citations given therein. The synthesis of the guanidine compounds according to the invention can proceed according to Schemes 1 or 2 under normal reaction conditions as, for example, described in Journal of Medicinal Chemistry 1997, 40, pg. 2462-2465, Journal of Medicinal Chemistry 1999, 42, pg. 2920-2926, Bioorganic & Medicinal Chemistry Letters 2001, 11, S. 523-528, Journal of Medicinal

Chemistry 2000, 43, pg. 3315-3321, Journal of Organic Chemistry 1991, 56, pg. 2139-2143 or Bioorganic and Medicinal Chemistry 2003, 11, 1319-1341.

Scheme 1:

Hetaryl amines II are commercially available or producible according to methods known in the literature (for example, Houben-Weyl, Methoden der organischen Chemie, Volume E8b and E8c, Stuttgart, 1994; M.B. Smith, J. March, March's Advanced Organic Chemistry, New York, 2001). The amines IV used in the synthetic path shown in Scheme 1 are also commercially available or can be prepared according to known protocols (e.g., Houben-Weyl, Methoden der organischen Chemie, 4th Edition, Volume XI/1, Stuttgart, 1957).

For the case that the moiety Q is a substituted thiazole moiety, the guanidine compounds of the general Formula I according to the invention can be constructed in one of the last steps according to Scheme 2. For this, one uses  $\alpha$ -haloketone V, which is commercially available or can be prepared according to the literature (e.g., Houben-Weyl, Methoden der organischen Chemie, 4th Edition, Volume VII/2c/, Stuttgart, 1977).

Scheme 2:

The use of the intermediate IVA for the preparation of the guanidines according to the invention proceeds according to methods known to one of ordinary skill in the art, as for example described in the literature cited above.

The guanidine compounds according to the invention as well as the intermediates possibly obtained can be isolated in the conventional way as well as, if necessary, purified, for example, by recrystallization from common organic solvents, preferably a short chain alcohol such as ethanol, or by chromatographic techniques.

Depending on the starting materials, the guanidine compounds according to the invention of the formula are obtained in free form or already as acid addition salts. The compounds in free form as well as salts of these compounds resulting according to the method can be transformed into desired acid addition salts or into the free form in a known manner.

The following examples illustrate the invention without restricting it. It should be noted that the notation and the formulaic representation of salts with protonated nitrogen reflects only one of many included possibilities with regard to the distribution of charge. This also applies for tautomeric forms.

To 13.0 g (84.92 mmol) 3-chloro-2-methylanisole in 80 ml CCl<sub>4</sub> at reflux were added 0.4 g dibenzoyl peroxide and then, subsequently and portion-wise, a mixture of 15.2 g N-bromosuccinimide and 0.4 g dibenzoyl peroxide. After completion of reaction the mixture was evaporation-concentrated, the residue was dissolved in dichloromethane, was sequentially washed with water and

saturated NaCl solution, was dried over  $\text{MgSO}_4$ , was filtered and again evaporation-concentrated. 20.8 yellow oil.

132.2 2-chloro-6-methoxy-benzylamine hydrochloride

13g di-tert butyliminodicarboxylate dissolved in 40 ml DMF were added drop-wise to a suspension of 24 g NaH (60% dispersion in mineral oil; de-oiled with n-pentane) in 20 ml DMF at 5°C. After 1 hour 15 g 2-chloro-6-methoxy-benzylbromide (crude product 131.1), dissolved in DMF were added, a further 100 ml of DMF were added to the mixture and the mixture was stirred overnight at room temperature. For the workup, excess NaH was destroyed by addition of 20 ml DMF-water 1:1, the mixture was subsequently evaporation-concentrated until dry and the residue obtained was dissolved in dichloromethane, was sequentially washed with 0.1n HCl and saturated NaCl solution, was dried over  $\text{MgSO}_4$ , was filtered and was evaporation-concentrated once again. Mixing of the thusly obtained oily residue with cyclohexane yielded 11.9 g of a beige solid, which were reacted further without being further purified.

For the Boc removal, 60 ml of 4n HCL in dioxane was added to 11.6 g of solid in 60 ml dichloromethane and was heated for 2 hours at 70°C. Evaporation concentration of the reaction mixture and treatment of the obtained oil with n-pentane yielded 6.0 g of 2-chloro-6-methoxy-benzylamine hydrochloride as an amorphous solid, ESI-MS  $[\text{M}+\text{H}^+]$  = 172.05. For the further reactions the hydrochloride was transformed into the free base.

Finally, the methyl *N*-(5-methyl-4*H*-1,2,4-triazole-3-yl)imidothiocarbamate was brought to reaction with 2,6-dimethoxybenzylamine in ethanol at 130°C in the microwave (100 Watt) and the *N*-(2,6-dimethoxybenzyl)-*N'*-(5-methyl-4*H*-1,2,4-triazole-3-yl)guanidine was isolated following chromatographic purification on preparative HPLC (Merck: Chromolith RP-18E, 100-25; eluent water/acetonitrile/ 0.1 molar acetic acid).

**Biological tests**

**1. [<sup>3</sup>H]5-CT binding assay h5-HT<sub>5A</sub>**

Membranes from HEK293-cells, which permanently express the h5-HT<sub>5A</sub> receptor gene, were incubated in 100 mM Tris-HCl-buffer (pH 7.7), containing 1mM EDTA in the presence of 2.5 nM [<sup>3</sup>H]5-CT (600 µl total volume). The total binding is defined as the binding which is observed when the membranes are incubated alone in the presence of the radioligand. The inhibition induced by the compound is determined by incubation of cell membranes in the presence of the radioligand, and of different concentrations of the compound of interest. Unspecific binding is defined by the binding of [<sup>3</sup>H]5-CT, which is obtained by incubation of the membranes as for the total binding but in the presence of 10 µM methiothepine. Following an incubation of 75 minutes at 30°C the membrane suspension is filtered through GF/B-filters, wrapped in 0.03 % PEI, wherein a Skatron<sup>R</sup> harvest system is used. The radioactivity retained in the filter is quantified by liquid scintillation counting.

**2. Funktional assay for human 5-HT<sub>5A</sub> receptor ligands  
-serotonin-induced increase of GTP-Europium binding**

#### General description:

Stimulation of G protein-coupled receptors by suitable agonists leads to the binding of GTP to the  $\alpha$ -subunit of trimeric G-proteins, followed by the dissociation of the GTP-bound  $\alpha$ -subunit from the  $\beta\gamma$ -subunit and the activation of signal transduction. By using a Europium-labelled GTP-analog, GTP-Eu, the activation of a G-protein-coupled receptor by an agonist can be monitored as an increase in the binding of GTP-Eu to the receptor-G-protein-complex. After removal of unbound GTP-Eu, bound GTP-Eu can be quantified by measuring the time-resolved fluorescence emission in suitable detection apparatus.

Cell line: h5HT5A\_18.2\_SH-sy-5y, a human neuroblastoma cell line, which stably expresses the human 5-HT5A receptor.

Membrane preparation: Cell membranes are prepared according to a standard protocol in the presence of protease inhibitors and are partially purified by two sequential centrifugation steps at 40000xg. Aliquots are stored at -80°C.

#### Assay:

The assay is performed in filter plates with 96 wells (AcroWell-96, Pall Corp.). The receptor membranes diluted in assay buffer (2.5  $\mu$ M GDP, 100 mM NaCl, 3 mM MgCl<sub>2</sub>, 50 mM HEPES pH 7.4) are added to the filter plate (5  $\mu$ g receptor membrane/well). Test compounds are dissolved in 100 % DMSO and serial dilutions are added to the receptor membranes (DMSO final concentration 0.5 %). The reaction is started by addition of serotonin (final concentration 1  $\mu$ M, total assay volume 100  $\mu$ l). After a first incubation period of 30 min at 30°C, GTP-Eu (final concentration 10 nM) is added, followed by a second incubation period of 30 min at 30°C. The reaction is stopped by rapid vacuum filtration and the wells are washed twice with ice-cold assay buffer. Bound GTP-Eu is measured in a VICTOR multilabel counter (PerkinElmer Corp.) using the time-resolved Europium settings. The data are corrected with respect to the unspecific binding and IC<sub>50</sub> values are calculated with PRISM 4.0 (GraphPad Inc.) using standard non-linear curve-fitting algorithms. K<sub>b</sub> values are calculated from IC<sub>50</sub> values using the Cheng-Prusoff approximation.

In both assays, different concentrations of the test substances are used, and the  $K_i$  or the  $IC_{50}$  values are determined. The affinity of selected compounds is shown in the following table:

**Table 1** Affinity to 5-HT5A (Ki)

+ means an affinity >500 nM
